High Intensity Beam Problems Near Transition

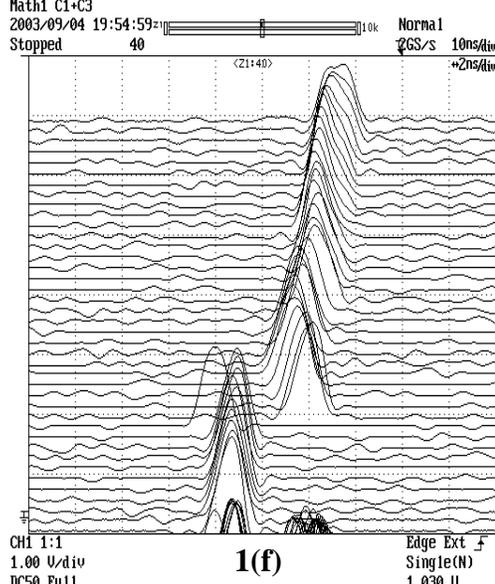

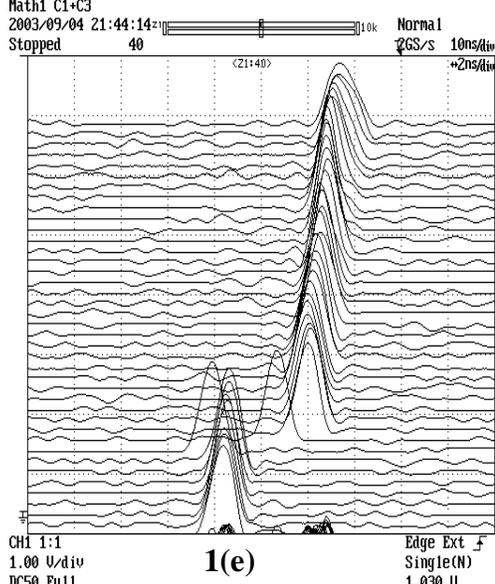

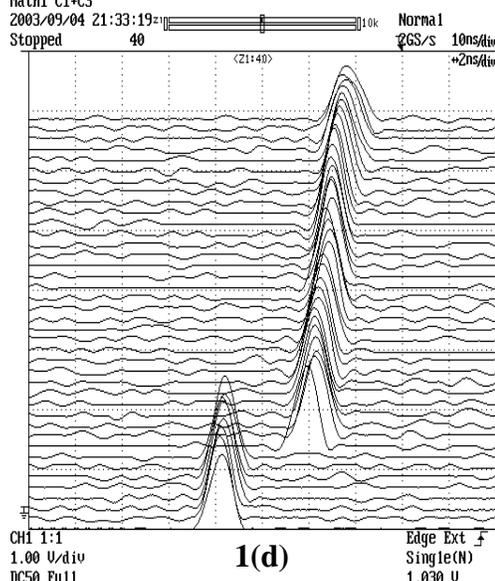

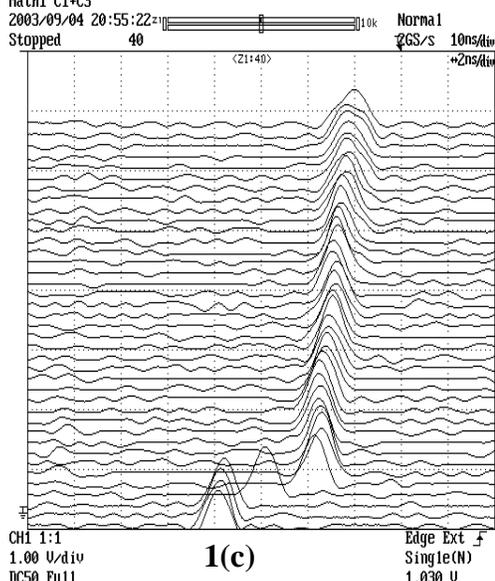

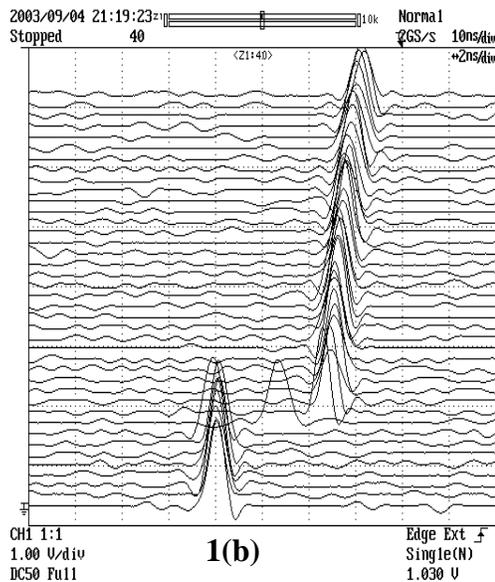

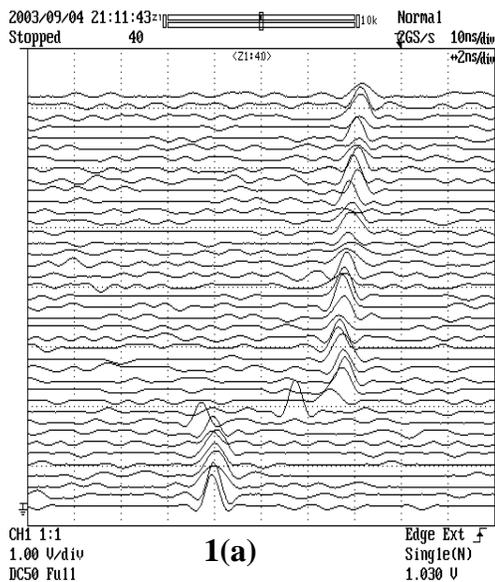

- Synchronous phase perilously close to 90° both sides of transition
- Real part of $Z_{||}$ crucial but uncertain
- Newly observed collective effect may complicate transition.
- New features in modeling code giving additional control and more complete information

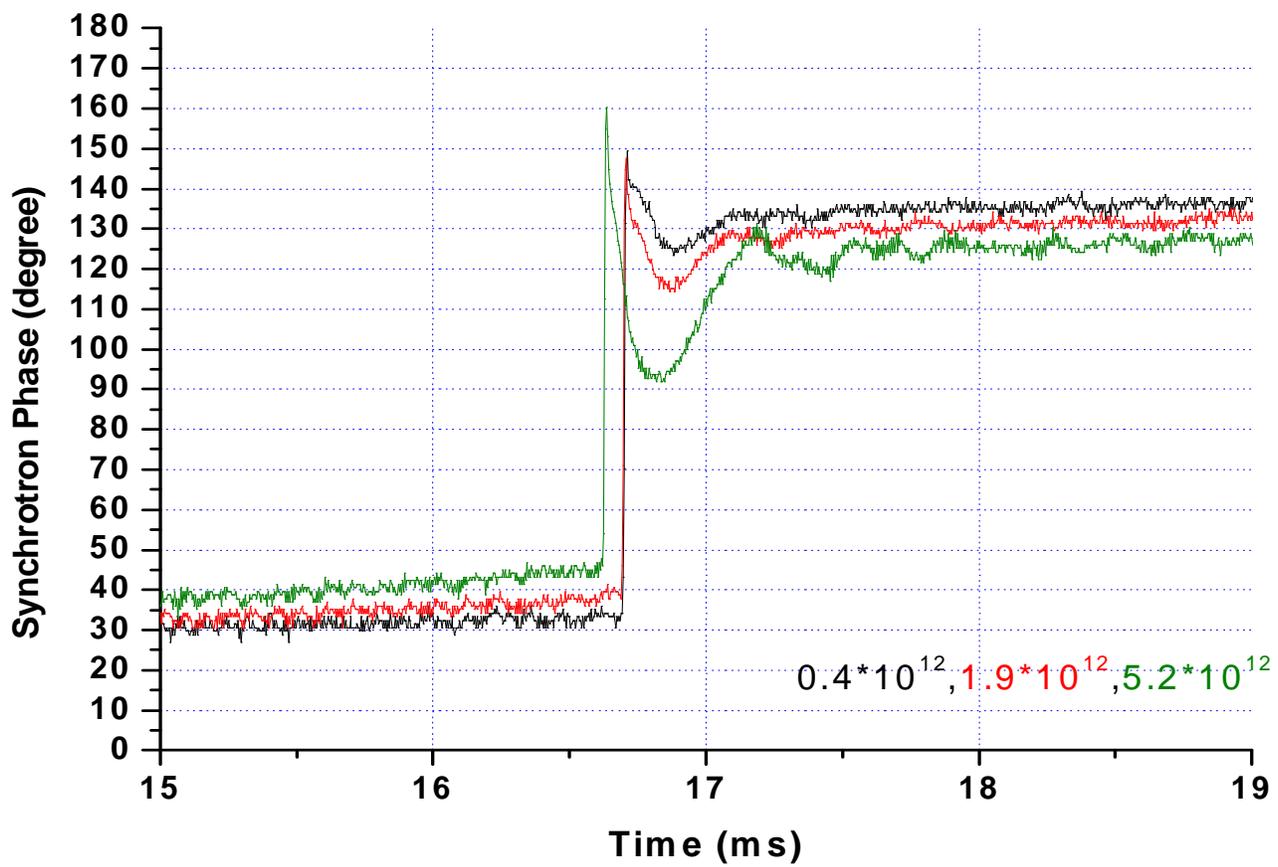

Symptoms of Trouble Now

There are clear signs of problems and impending difficulty. The next slide shows in a mountain range display, with traces every 8 turns bracketing transition, the approach of synchronous phase to 90° with increasing intensity. The six displays were recorded at intensities of .4, 1.2, 1.9, 2.6, 3.5, and 5.2×10^{12} .

In the following slide, the output of a phase detector comparing rf to beam is shown around transition for intensities of .4, 1.9, 5.2×10^{12} . Noteworthy features include the fast spike to incorrect phase of nearly 170° for highest intensity and the dip to nearly 90° following transition.

Transition Parameters analysis

γ_T	5.446	
$\dot{\gamma}$	419.2	s^{-1}
α_1 (ESME)	0.072	
rf amplitude	690.	kV
bunch area	0.0947	eVs
particles/bunch	$6 \cdot 10^{10}$	
harmonic number	84	
Transition energy	5.110	GeV
v/c at transition	0.9829	
rf frequency	52.20	MHz
circulation period	1.609	μs
\dot{E}	393.3	GeV/s
ϕ_s	1.161	rad
rms bunch length	0.5445	ns
geometric factor	4.515	
nonadiabatic time	0.2572	ms
nonlinear time	43.30	μs
$\eta_o(0)$ (Sorrenssen)	0.5107	
harmonic for $g_o/2$	23708	
fastest mode	13688	
“worst” mode	7903	
NMI threshold param.	1.372	
appx. peak current	6.696	A
$ Z_{ } $	29.19	Ω
$\frac{\Delta \epsilon}{\epsilon}$ (Jie Wei)	0.1280	

Parameters assumed in the modeling and derived quantities from the analysis of Sorrenssen, J. Wei, and W. Hardt.

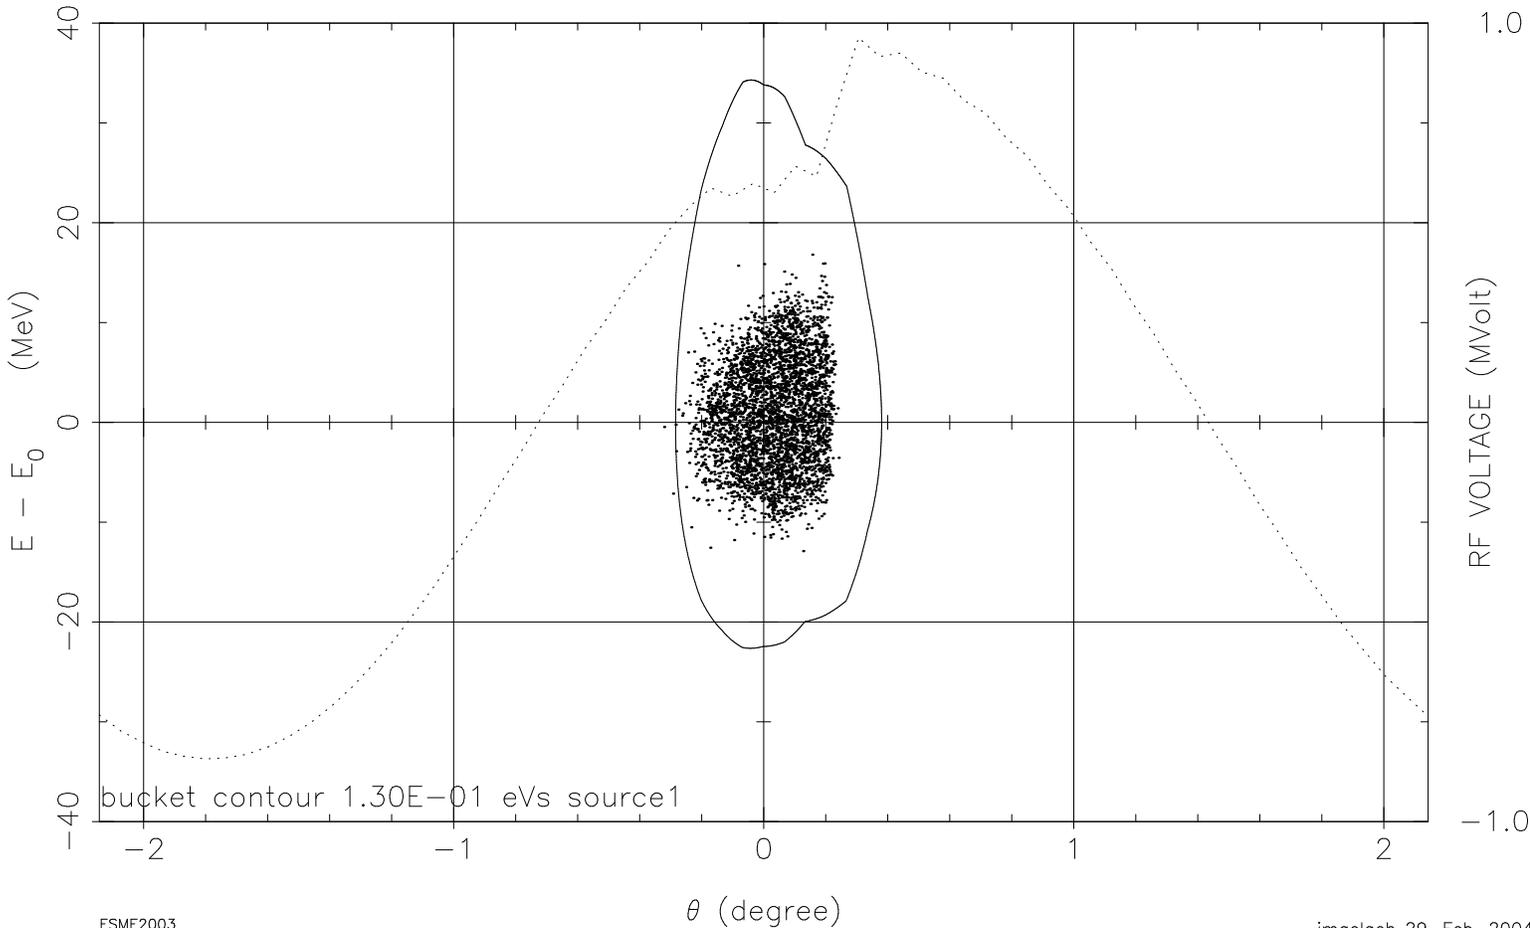

Modeling

There follows a series of selected ESME output from a case with $6 \cdot 10^{10}$ protons/bunch *before* capture. These are not exactly the transparencies shown during the talk; they were available only in hard copy and could not be reproduced exactly. Unfortunately, the transition loss of about 9 % is worse than the ~ 2.5 % in the transparency.

ESME2003

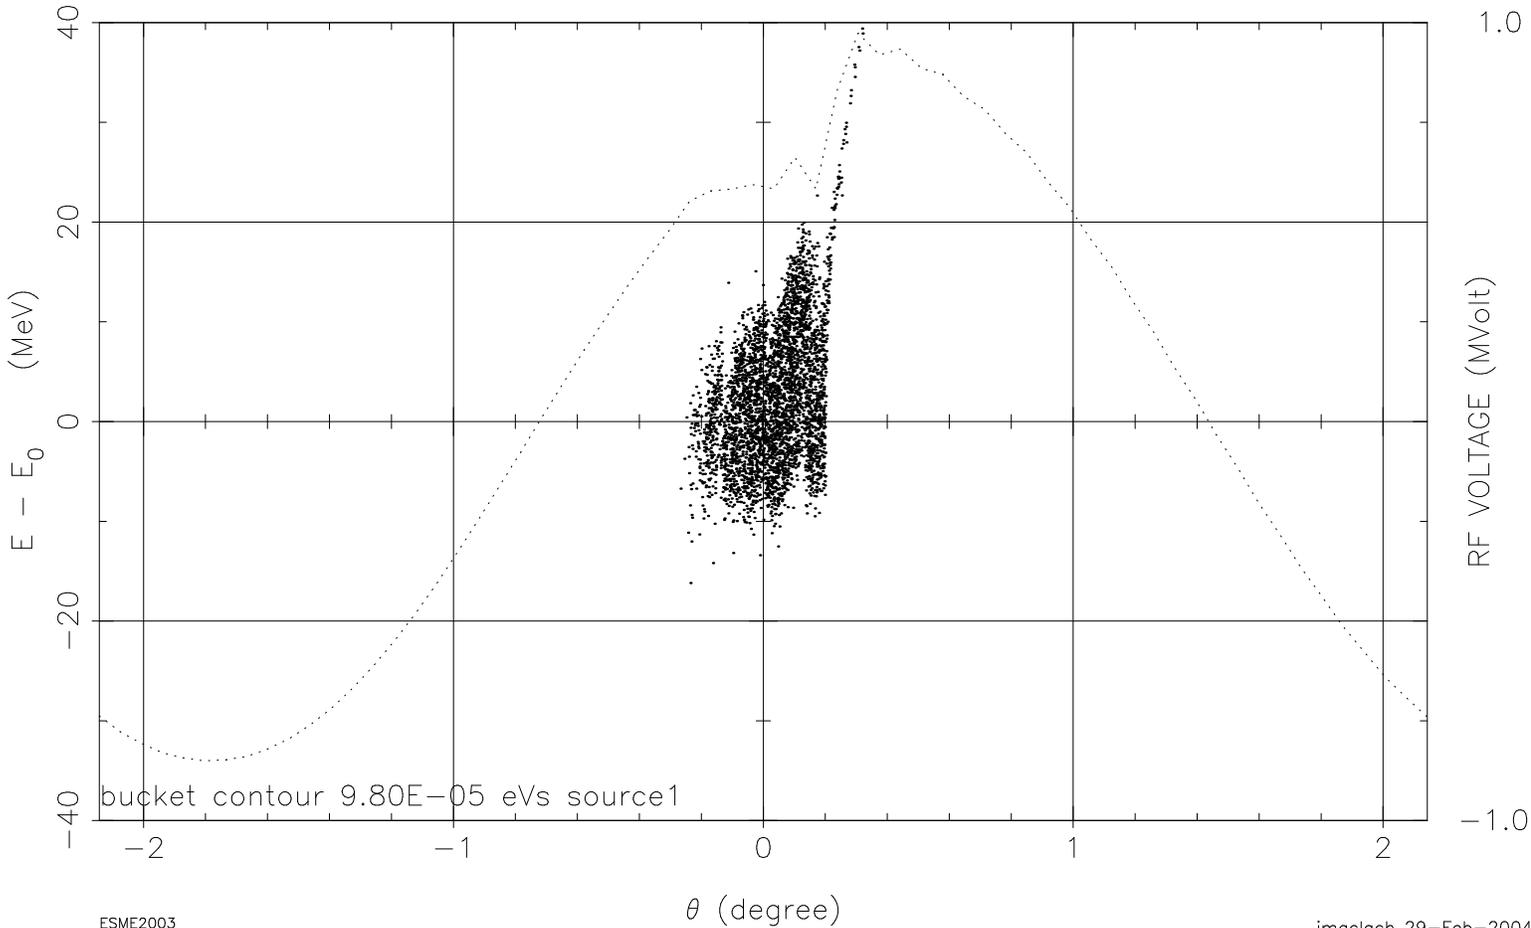

jmaclach 29-Feb-2004

A bunch of $6 \cdot 10^{10}$ protons just before transition. The dotted curve is the sum of rf potential and the collective potential calculated from Crisp magnet impedance measurements and perfectly conducting wall space charge impedance.

5 10^{12} p/b Jump at eta=.0003

Iter 9400 1.683E-02 sec

H_B (MeV)	S_B (eV s)	E_S (MeV)	h	V (MV)	ψ (deg)
1.9647E+00	9.8035E-05	5.1330E+03	84	8.616E-01	5.987E+01
ν_s (turn $^{-1}$)	pdot (MeV s $^{-1}$)	η			
5.9527E-04	3.7750E+05	3.0403E-04			
τ (s)	S_b (eV s)	N			
1.6088E-06	9.3478E-03	794927			

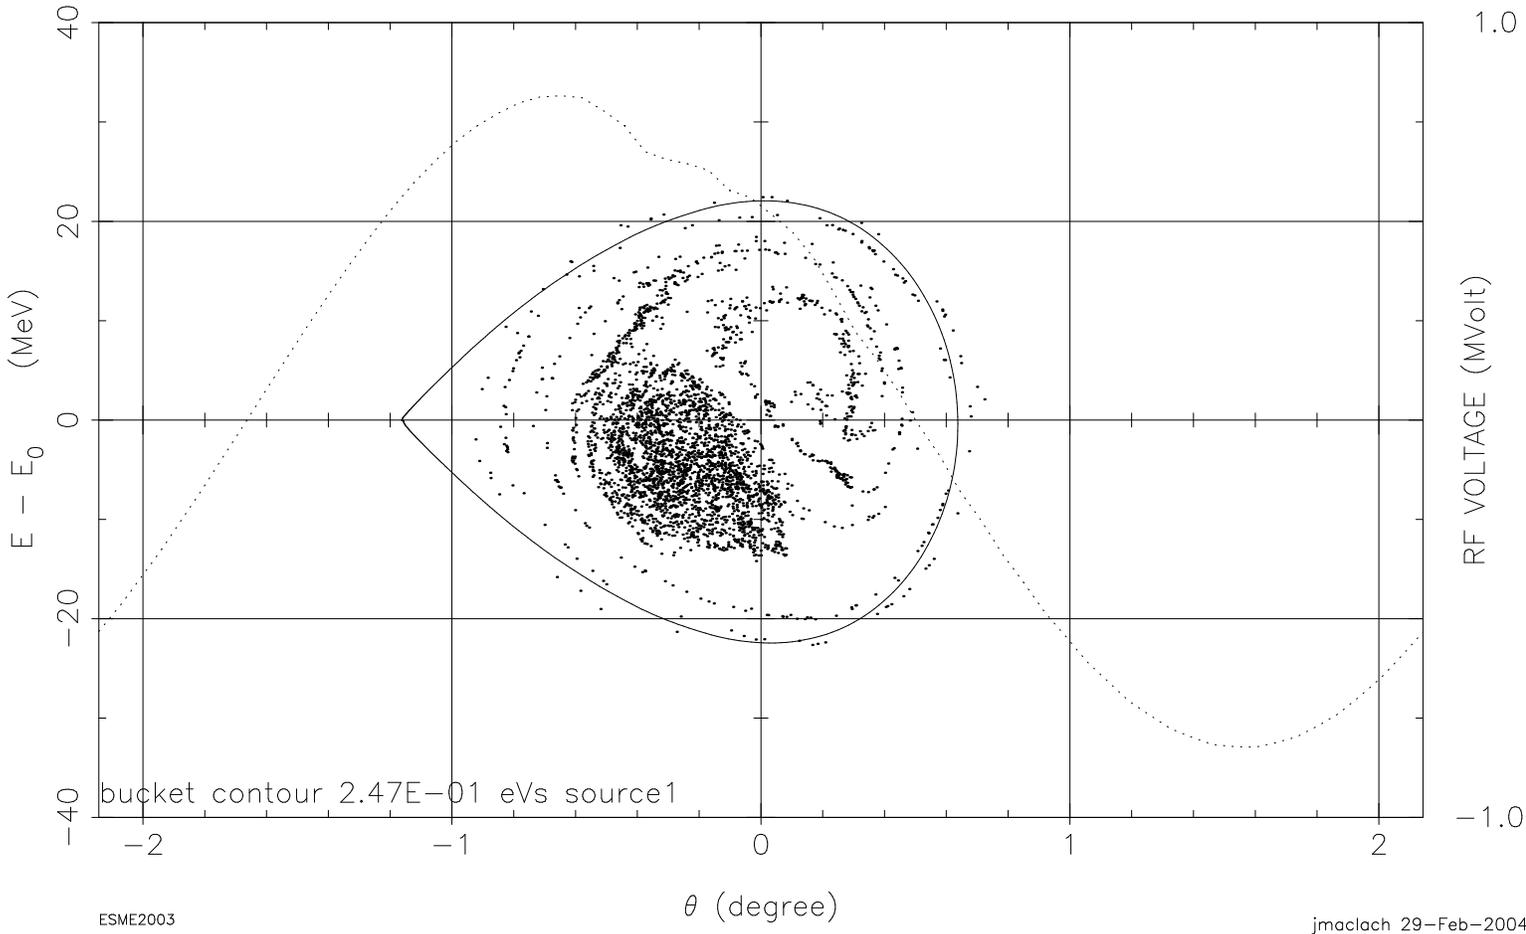

The same Booster bunch just after the transition phase jump. Note that the jump has been delayed until positive $\eta = 3 \cdot 10^{-4}$. This is a jump late by about $70 \mu\text{s}$.

5 10^{12} p/b Jump at $\eta = .0003$

Iter 13255 2.300E-02 sec

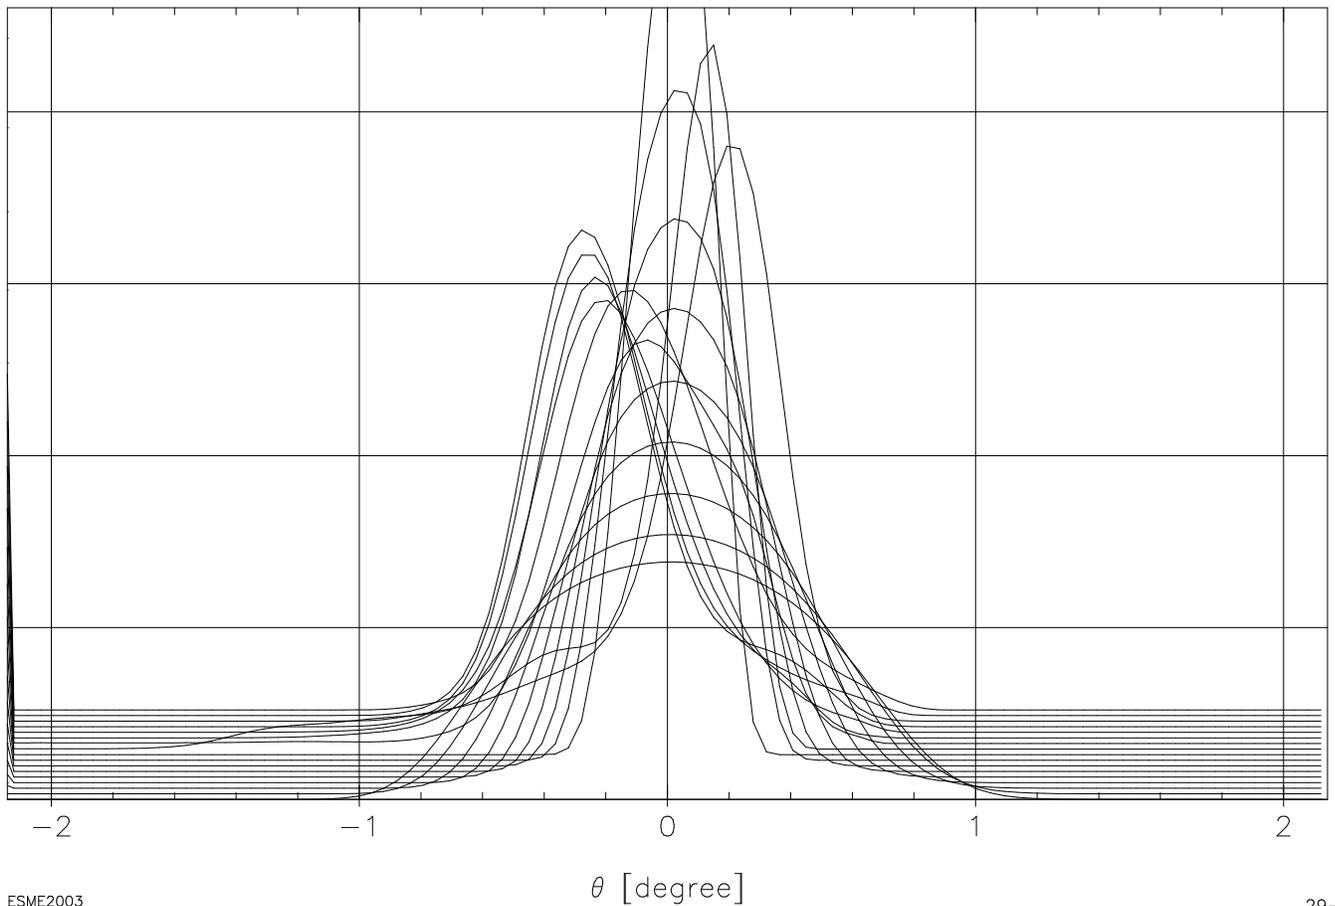

H_B (MeV)	S_B (eV s)	E_S (MeV)	h	V (MV)	ψ (deg)
2.2256E+01	2.4661E-01	7.2838E+03	84	8.303E-01	1.393E+02
ν_s (turn $^{-1}$)	pdot (MeV s $^{-1}$)	η			
4.4854E-03	3.0765E+05	1.7123E-02			
τ (s)	S_b (eV s)	N			
1.5950E-06	2.4926E-02	722755			

The same bunch at 23 ms. The total emittance is approximately .12 eVs ($5 \times$ the rms emittance).

5 10^{12} p/b Jump at eta=.0003
every 1000 turns, from turn 1000

Beam Current Profiles

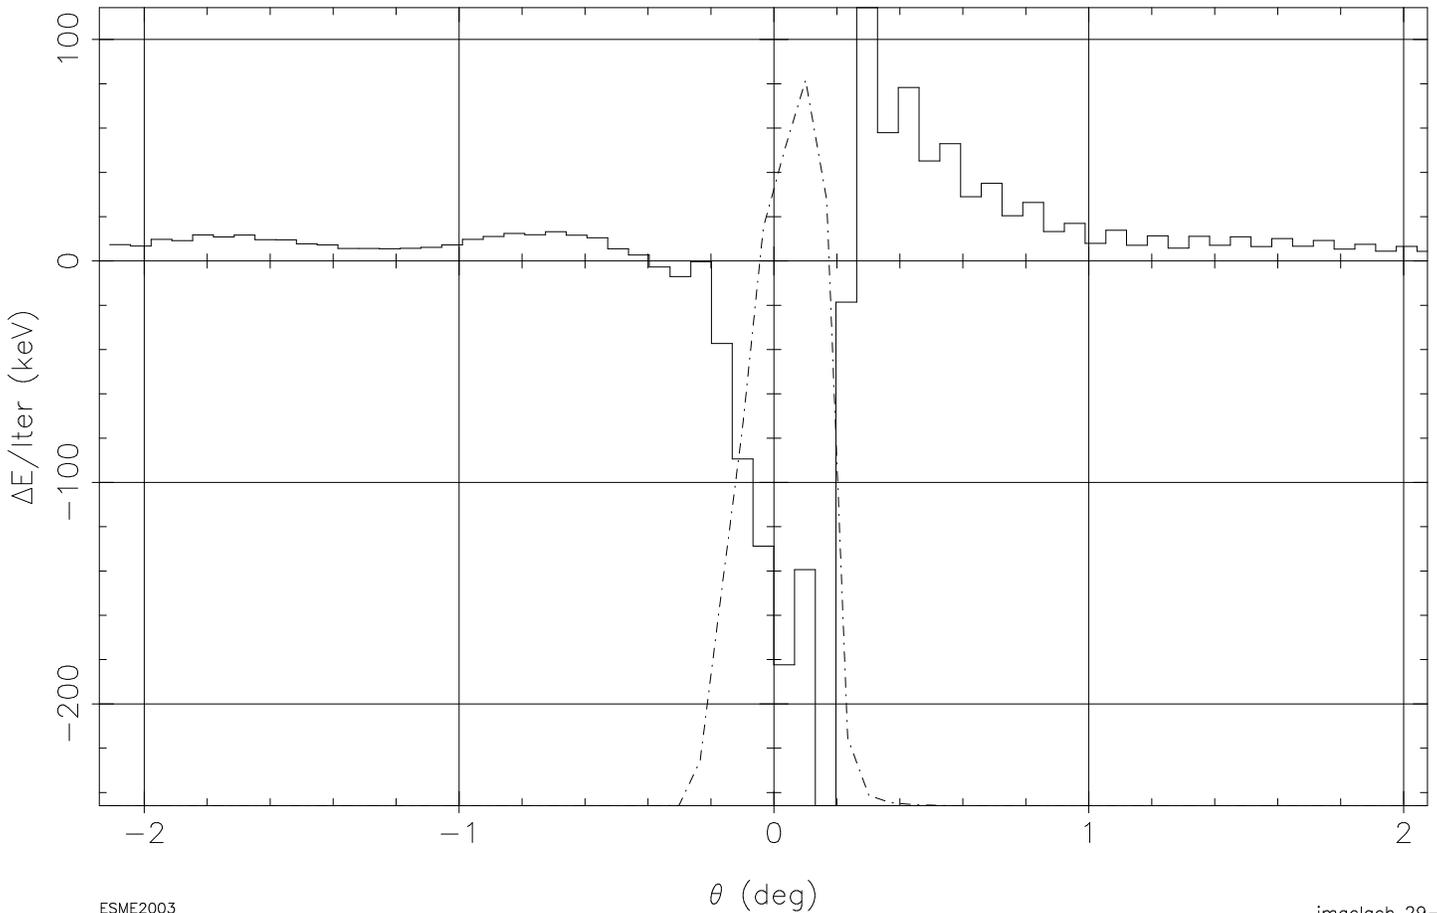

ESME2003

29-Feb-2004

The mountain range plotted every 1000 turns ($\sim 1.8 \mu\text{s}$) shows that the synchronous phase was generally correct; there is some lurching of the bunch to the inside and outside.

5 10^{12} p/b Jump at eta=.0003
Iter 9400
1.683E-02 SEC

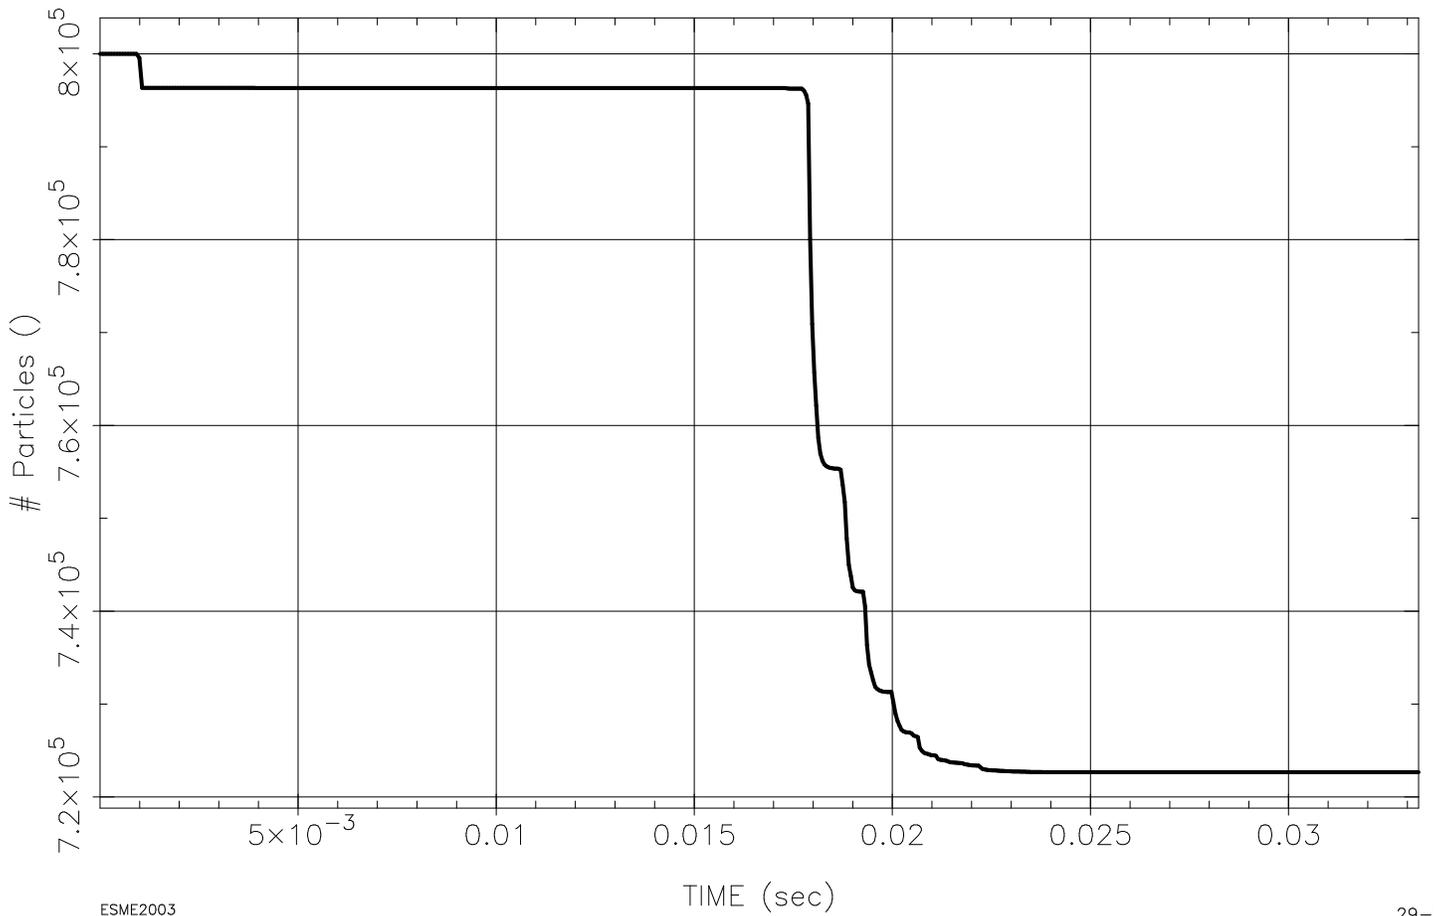

ESME2003

jmaclach 29-Feb-2004

The collective potential at transition. Notice the real energy loss per turn to the longitudinal coupling impedance. This curve does not include the beam loading of the rf cavities.

5 10^{12} p/b Jump at eta=.0003
Particles VS TIME

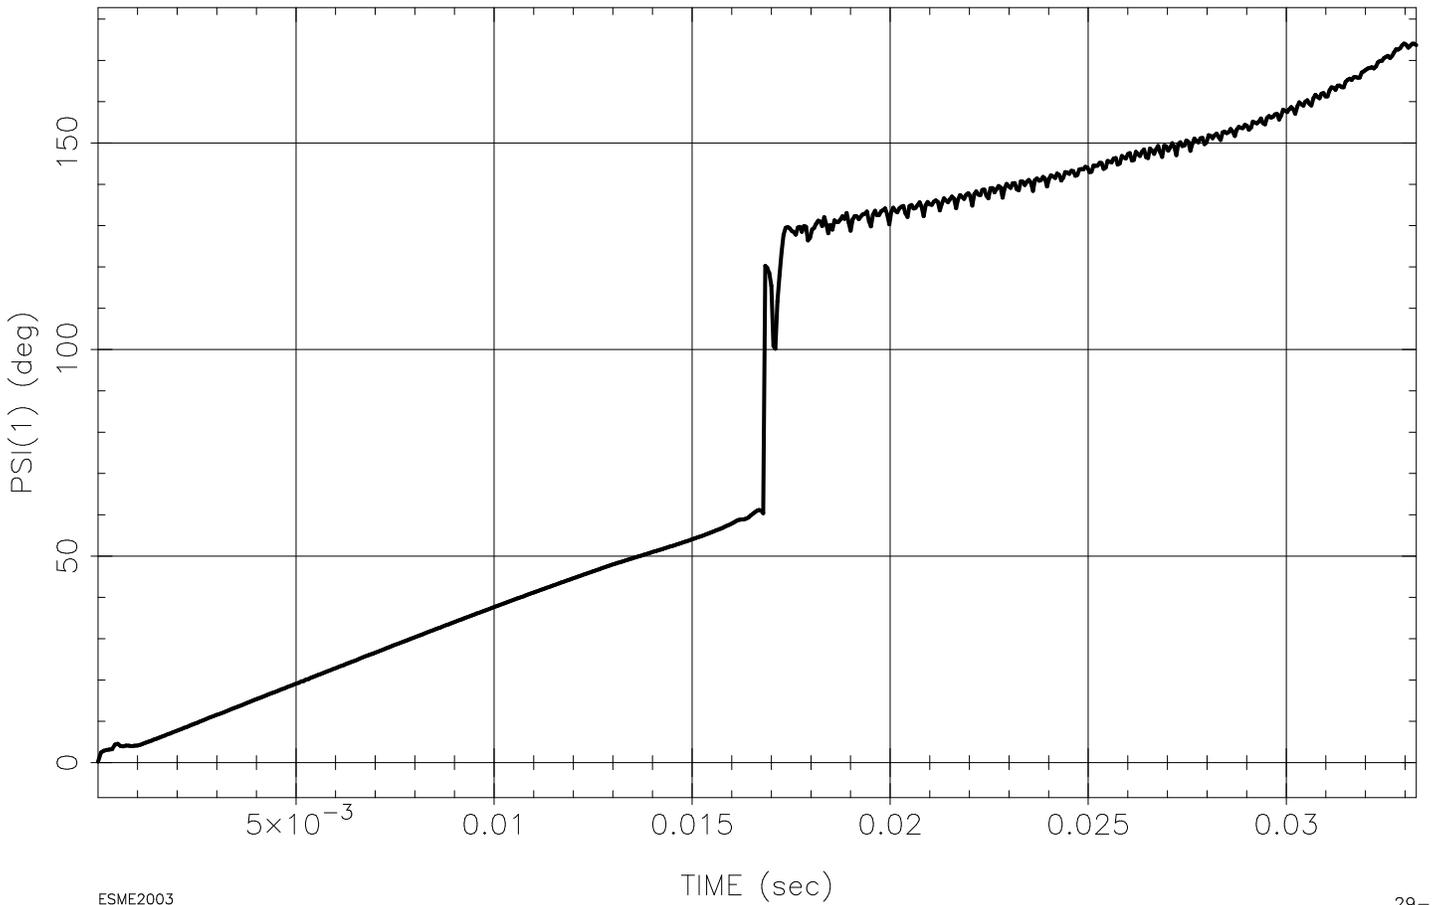

ESME2003

29-Feb-2004

Particle loss through the entire Booster cycle. The transition loss is about 9 %.

5 10^{12} p/b Jump at eta=.0003
PSI(1) VS TIME

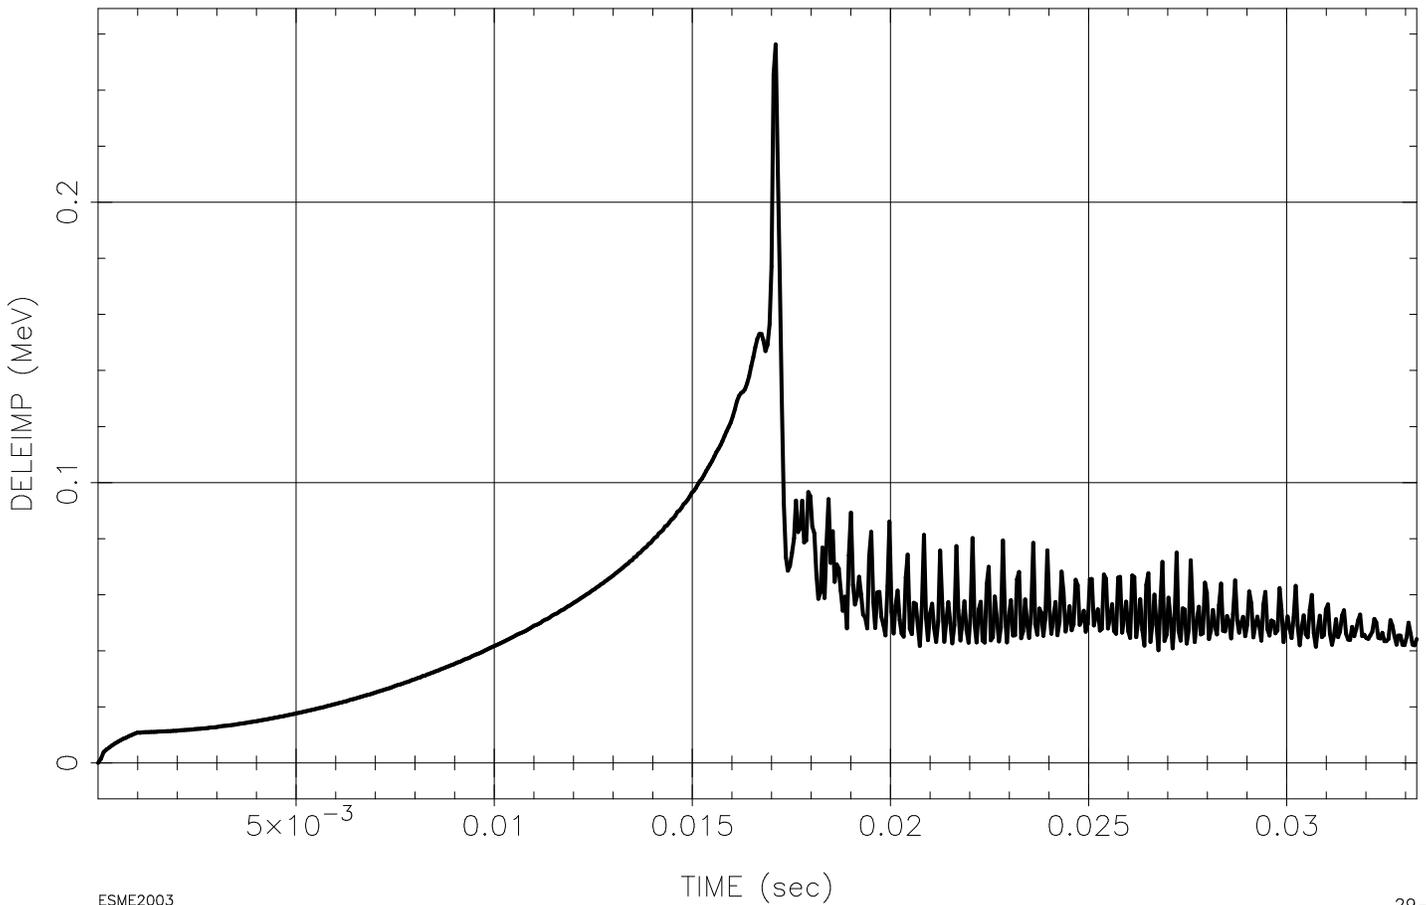

ESME2003

29-Feb-2004

The synchronous phase throughout the Booster ramp.

5 10^{12} p/b Jump at eta=.0003
DELEIMP VS TIME

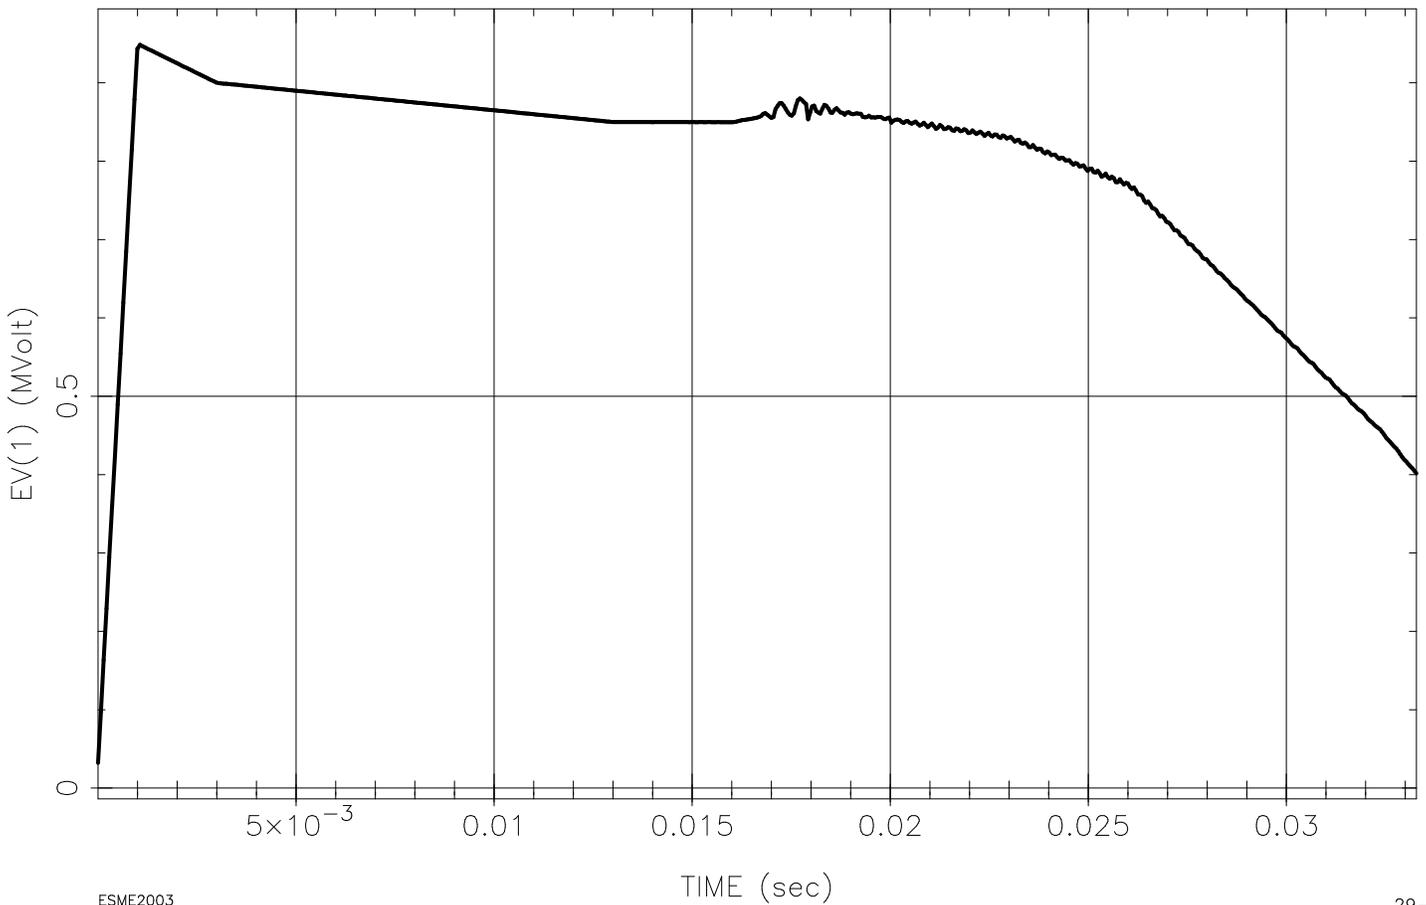

ESME2003

29-Feb-2004

The energy loss per turn to real part of longitudinal impedance (without cavity impedance) throughout the Booster ramp.

5 10^{12} p/b Jump at eta=.0003
EV(1) VS TIME

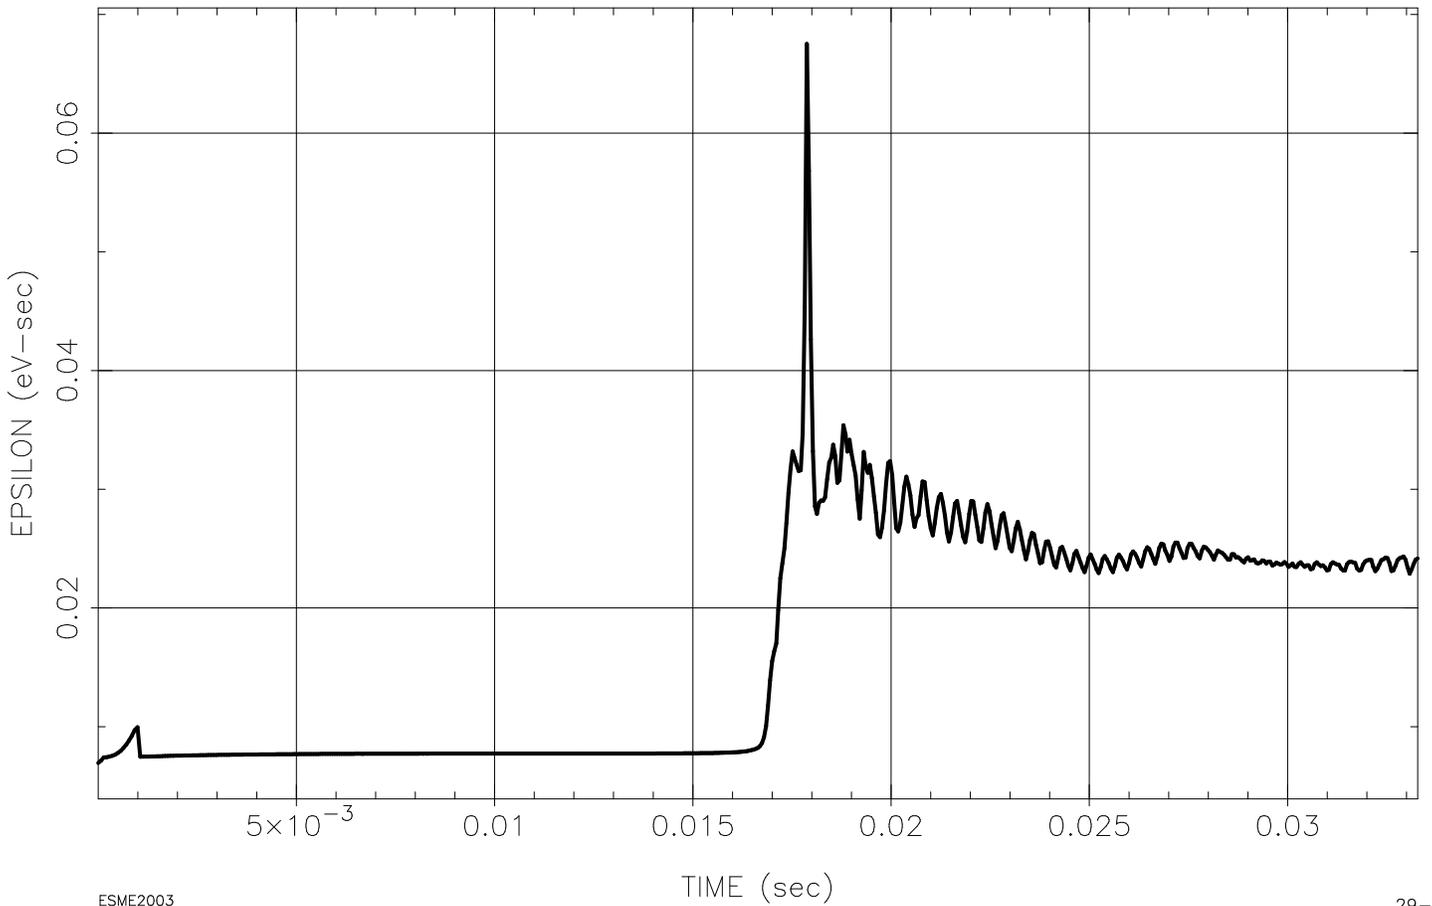

ESME2003

29-Feb-2004

The rf voltage curve; the wiggles after transition result from an attempt to damp the shape oscillation.

5 10^{12} p/b Jump at eta=.0003
EPSILON VS TIME

ESME2003

29-Feb-2004

The statistical (rms) emittance during the Booster ramp. The dilution after all loss is about a factor three, giving a total bunch area of approximately .12 eVs.

New Facilities for Macroparticle Tracking in E, φ

The modeling looks plausibly close to actual Booster performance except, perhaps, for the > 100 kV energy loss to the real impedance near transition. Perhaps the impedance estimate is larger than the actual value. Modeling in this detail has been made possible, or at least practical, by new multiparticle features in ESME.

- synchronization including energy loss to real impedance
- optional history of energy loss to real impedance
- optional plot of rf potential plus collective potential
- number of macroparticles can be increased or reduced during the course of a tracking run to accommodate differing needs in collective potential calculation
